

- Changing an item from optional to mandatory
- Deprecating parts of the device type definition

7.16.2. Device Type Composition

A device type definition MAY be a composed device type and therefore require other device types for its composition. A device type instance MAY be composed of other endpoints that support extra cluster instances. See [Chapter 9, System Model Specification](#) for more details.

7.16.3. Device Type Classification

Each device type definition SHALL specify the endpoint as being either a Utility, or Application. Each device type definition SHALL specify the scope as either endpoint or node. Each Application device type definition SHALL specify the endpoint as being either Simple or Dynamic.

7.16.3.1. Utility Device Type

A Utility device type supports configuration and settings. A utility device type definition SHALL define requirements for utility clusters. A utility device type MAY also represent the physical device or product. There MAY be more than one endpoint supporting a utility device type on a node.

Examples of utility device types: Root Node, Power Source, Bridged Node.

7.16.3.2. Application Device Type

Application devices types are typically the most common endpoints on a node and in the network. An endpoint supporting an application device type is an application endpoint. An Application device type SHALL be scoped to the endpoint. An application endpoint SHALL support clusters the primary application function of the endpoint.

Examples of application device type categories: HVAC, lighting, sensing, etc.

7.16.3.3. Simple Device Type

A Simple device type supports local control that is persistent, independent, and unsupervised. A Simple device type is an Application device type. Simple devices types are typically the most common endpoints in the network. Simple device type examples: sensors, actuators, lights, on/off switches, on/off power outlets, etc. Simple endpoints support independent operation without central control or gateways. An endpoint supporting a simple device type is a simple endpoint. Simple endpoints SHALL support relationships through bindings.

7.16.3.4. Dynamic Device Type

A Dynamic device type supports intelligent and supervisory services, such as commissioning, monitoring, trend analysis, scheduling and central management. A dynamic device type is an application device type. An endpoint supporting a dynamic device type is a dynamic endpoint. A dynamic endpoint is typically found on a central controller where there exists an intelligent supervisory application that manages simple device control applications. Typically, a dynamic endpoint supports client clusters for central control, management, monitoring or supervisory functions. Typically, the prod-
